## CYTOTOXIC AMINOSUGAR AND RELATED SUGAR DERIVATIVES OF INDOLOPYRROLOCARBAZOLES

### I. Field of the Invention.

5       The present invention relates to amino sugar and other sugar derivatives of indolopyrrolocarbazoles, their salts and hydrates, some of which compounds exhibit topoisomerase-I activity, are useful in inhibiting proliferation of tumor cells, are useful by exhibiting antitumor effect, and to a process for the preparation thereof.

### 10    II. Description of the Prior Art.

Indolo[2,3-a]carbazole alkaloids such as rebeccamycin (U.S. Pat. Nos. 4,487,925 and 4,552,842) and its water-soluble, clinically-active analog, 6-(2-Diethylaminoethyl)rebeccamycin (1) (U.S. Pat.No. 4,785,085) are useful antitumor agents which target DNA.

15

Topoisomerases are vital nuclear enzymes which function to resolve topological dilemmas in DNA, such as overwinding, underwinding and catenation, which normally arise during replication, transcription and perhaps other DNA processes. These enzymes allow DNA to relax by forming enzyme-bridged strand breaks that act as transient gates or pivotal points for the passage of other DNA strands. Topoisomerase-targeting drugs appear to interfere with this breakage-reunion reaction of DNA topoisomerases. In the presence of topoisomerase active agents, an

20

aborted reaction intermediate termed 'cleavable complex' accumulates and results in replication/transcription arrest which ultimately leads to cell death. The development of topoisomerase I active agents, therefore, offers a new approach to the multi-regimental arsenal of therapies currently used in clinics for the treatment of cancer.

The article in Cancer Chemother. Pharmacol (1994), 34 (suppl): S 41-S 45 discusses the Topoisomerase-I active compounds that are in clinical studies and these agents are found to be effective in clinical anti-tumor studies. Structurally these clinical candidates are related to the

Camptothecin alkaloid (2)

European Patent Application publications 0 545 195 B1 published

- November 22, 1995 and 0,602,597 A2 published June 22, 1994 and in Cancer Research 1993, 53, 490-494 and 1995, 55, 1310-1315 disclosed indolo[2,3-a]carbazole derivatives (3) related to the Rebeccamycin class and claimed anti-tumor activity; however the major mechanism of action may not be Camptothecin like. Camptothecins act by Topoisomerase I mechanism.
- The world patent application WO 95/30682 also disclosed indolocarbazoles related to compound (3) and claimed anti-tumor activity.

Hudkins et. al. in WO96/11933 published on April 25, 1996 and its corresponding U. S. Pat. No. 5,475,110 disclosed a series of fused  
 5 pyrrolocarbazoles and showed in vitro biological data such as inhibition of neuronal choline acetyltransferase (ChAT), Protein Kinase C (PKC) inhibition for some compounds. U.S. Pat. No 5,468,849 discloses certain fluororebeccamycin analogs as useful antitumor agents, along with a process for their production by fluorotryptophan analog feeding of a  
 10 rebeccamycin-producing strain of *Saccharothrix aerocolonigenes*, preferably *Saccharothrix aerocolonigenes* C38,383-RK2 (ATCC 39243).

Glicksman et. al. in U.S. Patent No, 5,468,872 discloses indolocarbazole alkaloids which are different in structure from those of  
 15 formula I of the present invention.

Kojiri et. al. in WO96/04293 published on February 15, 1996 discloses indolopyrrolocarbazoles having a dissacharide substituent which is different than our amino-substituted sugar compounds.

20

There is nothing in any of the foregoing references, or in the general prior art, to suggest the novel cytotoxic amino-sugar and other

sugar derivatives of indolopyrrolo carbazoles, some of which are topoisomerase I active agents, of the present invention.

The compounds of the present invention are useful pharmacologic agents with anti-tumor properties. With Topoisomerase-I active  
20 properties, the compounds can be useful as anti-tumor agents. In recent years, numerous reports have surfaced the literature suggesting the role of Topoisomerase-I targeting drugs is to stabilize a covalent DNA-topoisomerase I complex to yield enzyme -linked DNA single-strand breaks. From a pharmacologic standpoint there are advantages to target  
25 Topoisomerase I; first relatively high levels of its presence in both proliferating and quiescent cells suggests that its function may be independent of cellular growth rate and second, topoisomerase I active agents may be effective in slow growing as well as rapidly proliferating

tumors. Cells from colon tumors have been shown to contain higher intracellular levels of topoisomerase I than normal mucosal cells suggesting the possibility for selective cytotoxic advantage. Thus, inhibition of proliferation of tumor cells by compounds of formula I was initially demonstrated by effective inhibition of topoisomerase I. Selected compounds of formula I, usually having EC<sub>50</sub> values less than 10 µM in the Topoisomerase I assay, were also tested in an inhibition of human/mouse tumor cell proliferation assay. Compounds of this invention were also examined for their therapeutic effect in vivo against mouse tumor (P388) and the results are shown in the following pharmacological test examples (Table 1 ).

#### In-Vivo Anti-Tumor Efficacy

In-vivo antitumor experiments were initiated by implanting mice (BDF1 or CDF1) ip with 10(6) P388 leukemia cells. Treatments were initiated one day after implant and involved one ip injection per dose level; several dose levels were evaluated per compound. Six mice were typically used per dose level in treatment groups, and eight to ten mice were used as parallel untreated leukemic controls. Evaluation of activity was made on the basis of comparing the median survival time (MST) of treated (T) mice with the MST of control (C) mice. Activity was defined as a %T/C of > or = 125%, calculated as:  $MST(T)/MST(C) \times 100 = \%T/C$

Topoisomerase I Activity (In-Vitro)

Topoisomerase I activity was measured as described below: The procedure for assaying compound induced, topoisomerase I mediated single strand break formation in DNA was essentially that described by Hsiang, et al., appearing in J. Biol. Chem. 260: 14873-14878 (1985). Samples dissolved in 100% DMSO as either 10  $\mu$ M or 10 mg/ml solutions, unless otherwise stated, were diluted in Tris-EDTA buffer. Marine bacteriophage PM2 DNA (Boehringer Mannheim) was also diluted in Tris-EDTA buffer to a concentration of 0.02  $\mu$ g/ $\mu$ l. Different dilutions of compound being evaluated were mixed with diluted DNA and this mixture was added to 1000 unit (one unit of enzyme activity is defined as the amount capable of relaxing 100 ng of supercoiled DNA in approximately 30 minutes at 37°C) aliquots of purified human topoisomerase I (Topogen) in 2X reaction buffer to start the reaction. The compound - DNA - enzyme mixture was incubated for 30 minutes at 37° C before stopping the reaction with warm stop buffer containing sodium dodecyl sulfate and proteinase K (Sigma). These mixtures were allowed to incubate at 37° C for another 10 minutes, at which time the mixtures were removed from the waterbath and

extracted with a 24:1 mixture of chloroform/isoamyl alcohol. Following centrifugation, aliquots of the aqueous phases were placed in wells of a 0.9% agarose (SeaKem) gel in Tris-borate buffer containing 0.5 µg/ml of ethidium bromide and subjected to electrophoresis for 15 hours to  
5 separate the different topological isomers and nicked and broken DNAs. After destaining the gel in water, the ethidium bromide stained DNA reaction products were visualized by exposing the gel to UV irradiation. Negatives of photographs of the irradiated gels were scanned with a densitometer and areas under the peaks were calculated in order to obtain  
10 percent single strand DNA break formation for each sample. A median effective concentration (EC<sub>50</sub>) was obtained for each compound by interpolation between points of the resulting dose - effect curve which defines the potency of the compound for its effect for inducing topoisomerase I mediated single strand breaks in DNA.

15

The topoisomerase I activity for selected compounds of the present invention is shown below in Table II.

The novel compounds of the present invention, as exemplified by amino and other sugar derivatives in Table II, show remarkable topoisomerase-I activity even in the sub-micro molar range of concentration. Apriory, this activity, however, is unexpected and not predictable by one in the skilled art since a small change in substitution patterns seems to result in a highly unexpected change in activity. This is exemplified by the topoisomerase I activity difference for the compounds prepared by Examples 18 and 19. Example 19 is an effective anti-tumor agent with sub micro molar Topo-I activity whereas Example 18 did not show Topo-I activity even at greater than 100 micro molar concentration. The only difference between the compounds of Examples 18 and 19 is that in Example 18 X<sub>1</sub> and X'<sub>1</sub> is 2, 10-difluoro and R<sub>6</sub> is amino, whereas in Example 19 X<sub>1</sub> and X'<sub>1</sub> is 3,9-difluoro and R<sub>6</sub> is hydrogen. Moreover, rebeccamycin, where X<sub>1</sub> and X'<sub>1</sub> is 1, 11-dichloro, R<sub>4</sub> is methoxy and R<sub>5</sub> is hydroxy, is also not Topo-I active.

In-Vitro Cell-Based Cytotoxicity Activity

The proliferation inhibition activity against human colon cell line was measured as follows.

- 5           Cytotoxicity was assessed in HCT116 human colon carcinoma cells by XTT (2,3-bis(2-methoxy-4-nitro- 5-sulfophenyl)-5-[(phenylamino)carbonyl]-2H-tetrazolium hydroxide assay as described in the literature by Scudiero, DA, Shoemaker, RH, Paull, KD, Monks, A, Tierney, S, Nofziger, TH, Currens, MJ, Seniff, D, and Boyd, MR.
- 10       Evaluation of a soluble tetrazolium/formazan assay for cell growth and drug sensitivity in culture using human and other tumor cell lines, was done according to the procedure described in Cancer Res. 48: 4827-4833, 1988. Cells were plated at 4000 cells/well in 96 well microtiter plates and 24 hrs later drugs were added and serial diluted. The cells were incubated
- 15       at 37° C for 72 hrs at which time the tetrazolium dye, XTT, containing phenazine methosulfate was added. A dehydrogenase enzyme in live cells reduces the XTT to a form that absorbs light at 450 nm which can be quantitated spectrophotometrically. The greater the absorbance the greater the number of live cells. The results are expressed as an IC<sub>50</sub> which is the
- 20       drug concentration required to inhibit cell proliferation (i.e. absorbance at 450 nm) to 50% of that of untreated control cells.

The results for selected compounds of the present invention are shown in Table III.

One aspect of the present invention involves administration of  
15 compound of Formula I or a pharmaceutically acceptable salt and or  
solvate thereof, to a mammal implanted with tumor or susceptible to  
cancer formation. In general the compound would be given in a dose  
range of from about 0.01mg/kg to about the MTD (maximum tolerated  
dose). Although the dosage and dosage regimen and scheduling of a  
20 Formula I compound must in each case be carefully adjusted, utilizing  
sound professional judgment and considering the age, weight and  
condition of the recipient, the route of administration and the nature or  
extent of the cancer disease condition. The term "systemic  
administration" as used herein refers to oral sublingual, buccal,  
25 transnasal, transdermal, rectal, intramascular, intravenous,  
intraventricular, intrathecal, and subcutaneous routes. In accordance  
with good clinical practice, it is preferred to administer the instant

compounds at a concentration level which will produce effective beneficial effects without causing any harmful or untoward side effects.

### DESCRIPTION OF THE SPECIFIC EMBODIMENTS

The procedure for the preparation of formula I compounds is illustrated in Scheme I, and the preparation of the key intermediates/starting materials is illustrated in Scheme II.

wherein:

10 y = Br or Cl;

R' = H;

R''' = H or a monosaccharide derivative;

R'' = H or aryl or heteroaryl

Scheme II

Key Intermediates

- In schemes I and II,  $R_2$  to  $R_6$ ,  $X_1$ ,  $X_2$ ,  $X_1'$ ,  $X_2'$  and Q are as defined supra. PG is a synthetic organic "protecting group" of the type generally used to "protect" an hydroxyl functionality e.g. an acyl type group such as an acetyl, trifluoroacetyl or an arylalkyl group like benzyl group or the like. Suitable "protecting" or "blocking" groups used in organic synthesis are well known to the practitioner and are adequately described in the appropriate literature. See, e.g. Theodora Greene, Protective Groups in Organic Synthesis, John Wiley and Sons, New York.
- The starting materials in Scheme I are di-halo maleimide derivatives (II), such as 3,4-dibromomaleimide; and the substituted indole derivatives of formula III. Addition of indole derivatives III ( $R'' = \text{H}$  or Ar) to maleimide II in the presence of a base like ethylmagnesium bromide or the like in organic solvents like THF (i.e. tetrahydrofuran), benzene or toluene or combinations thereof at  $-20^\circ\text{C}$  to reflux temperature would result in mono and bis derivatives V and IV respectively. The amount of reactants can be controlled to vary the product ratio of V vs IV to one's

favor. Intermediate IV can be further transformed into indolopyrrolocarbazole core VI by using oxidative cyclization conditions such as Dicyanodichloroquinone (DDQ)/acid/heat or palladium acetate/acid or iodine, light and the like. Glycosylation of VI with reactive

5 sugar derivatives like the 1,2-epoxide described in publications J. Org. Chem. 1993, 58, 343-349 and J. American Chemical Society 1989, 111, 6661-6666 or 1-halo and others in the presence of an appropriate base such as diisopropylethyl amine, hexamethyldisilazide, to form the mono- or di- or tri- anion of the indolopyrrolocarbazole core VI in organic solvent like

10 THF, DMF (i.e. dimethylformamide), dioxane, benzene, DME (i.e. dimethoxyethane) produces the fully protected derivative VIII. Alternatively, more preferably, glycosylation may also be achieved by reacting the 1-hydroxy form of an appropriately protected sugar derivative with the core VI under the well known Mitsunobu procedure [PPh<sub>3</sub>/

15 dialkylazidodicarboxylate] in ethereal solvent like THF or chlorinated solvent like CH<sub>2</sub>Cl<sub>2</sub>. Appropriate sugar derivative for the glycosylation may be obtained by selective modification of the different hydroxyl groups employing literature methods. For example, the article appearing in J. Carbohydrate Chemistry (1995), 14 (9), p1279-94 discloses the 6-halo-6-

20 deoxy glucose derivative. Another method to obtain compound VIII involves glycosylation of the mono adduct first under the conditions described above to give the intermediate VII followed by dehydrohalogenation and cyclization using a number of well known method published in the art for such a transformation including heat or

25 shining UV irradiation to a solution VII in solvents like Dioxane, Ethanol or an appropriate mixture of solvents. The compound VIII is a protected form of Formula I. Judicious choice of the protecting group in the sugar would allow selective manipulation of the primary hydroxyl group. For

example, when the primary 6'-hydroxyl group was protected with the p-methoxybenzyl protecting group (PMB) and the rest of the hydroxyls were protected with simple benzyl groups (Bn), it is possible for one skilled in the art to remove the PMB group without deprotecting the benzyl group.

- 5 In this manner, the primary 6-hydroxyl group is oxidized to give the corresponding acid, and their ester and amide derivatives. Furthermore, under controlled oxidation conditions using Dess-Martin reagent or the like, the 6-hydroxyl group is oxidized to the corresponding aldehyde.

- Treatment of the aldehyde with the well known fluorinating reagent like  
10 DAST resulted in the 6-difluoromethyl derivative. Similarly, other hydroxyl groups were also modified. For example, when the 4-hydroxyl group of the galactose sugar derivative (hexose sugar in pyranose form in which the 4-hydroxyl is orienting the axial position) can be used to modify the 4-position. Oxidation of the 4-hydroxyl group of the appropriately  
15 protected sugar derivative furnished the ketone which could be further functionalized to different derivatives including the 4-difluoro derivative employing the known procedures. If the 4-hydroxyl group is activated, for example in the case of 4-mesylate, it is susceptible for nucleophilic displacement by agents such as an azide (e.g. sodium azide) to provide 4-  
20 azido derivative. On the other hand, when the sugar derivative with the unprotected 4-hydroxyl group is treated with the fluorinating agent, DAST, one obtains the 4-fluoro derivative. Similarly, other hydroxyl groups are also selectively modified. For example modification of the published literature procedure allows for introduction of a fluorine atom  
25 at the 2-position of the sugar (Bioorg. Med. Chem., Vol. 5, No. 3, pp. 497-500 (1997). This is illustrated in example 90. Simple protecting group manipulation such as hydrogenation or transfer hydrogenation with Pearlman's catalyst to remove the benzyl protecting groups of the sugar

moiety or if necessary, hydrolysis with KOH or NaOH of the maleimide nitrogen protecting group to give the anhydride after an acid workup followed by heating with an appropriate amine would produce the desired Formula Ia with the correct substitution pattern. Selective derivatization of each hydroxyl group in the sugar moiety of compound Ia may be achieved by using the protecting group manipulation and removal of the primary hydroxyl protecting group, in the presence of the secondary hydroxyl protecting groups. For example, when the compound of formula Ia, in a glucopyranosyl form (i.e. hexose formula (B)), wherein all the sugar hydroxyl groups are free, is treated with a silyl reagent like trimethylsilyl or t-butyl-di-phenyl silyl or preferably t-butyl-di-methylsilyl triflate in the presence of a base in a solvent like  $\text{CH}_2\text{Cl}_2$  or THF at cold or room temperature one obtains the derivative wherein the 3 and 6 positions are protected as silylethers. Selective deprotection of the 6 position silylether may be achieved under controlled aqueous mineral or organic acid conditions such as trifluoroacetic acid and water mixture as a solvent at cold temperature such as  $-25^\circ\text{C}$  to  $0^\circ\text{C}$  over a period of 30 minutes to 3hrs or until the reaction is over as followed by thin layer chromatography. This intermediate is now set for further derivatization at the 6-position to activate the 6-hydroxyl to a good leaving group like mesylate or halide. Thus, methanesulfonyl or toluenesulfonyl or trifluoromethanesulfonyl chloride in the presence of a base like triethylamine or pyridine would produce the corresponding mesylate or tosylate. Alternatively, selective mesylation of the primary 6-hydroxyl group may also be achieved directly from compound of Formula Ia wherein all sugar hydroxyl groups are unprotected under pyridine and mesyl chloride in pyridine at  $0^\circ\text{C}$ . Nucleophilic displacement with an appropriate amine or other nucleophiles like azide followed by reduction

of the azide to amine would then produce desired compounds of formula I such as 6' amino sugar derivatives I b. In this manner, the 6-methyl sulfide derivative was prepared employing either the sodium salt of the thiol derivative or the thiol and a base like K<sub>2</sub>CO<sub>3</sub> in DMF or an organic amine base like triethylamine or Hunig's base at varying temperatures from room temperature to 150°C. The 6-alkyl sulfide, for example 6-methyl sulfide, is further oxidized by known oxidizing agents like Oxone or m-chloroperbenzoic acid or, preferably, monoperoxyphthalic acid magnesium salt (MMPP) to their sulfoxides and sulfone under controlled conditions. Similarly, other hydroxyl groups may also be derivatized as desired. Yet another modification of the formula I would result in N-maleimide substituted (i.e. R<sub>6</sub>) indolopyrrolocarbazole derivatives Ic. For example, the anhydride obtained from the base hydrolysis of the appropriately protected form of Formula I may be reacted with a number of amine derivatives to produce the desired N-substituted maleimides.

As depicted in Scheme II, the N-substituted maleimide derivative may be obtained either directly from the dihalomaleic anhydride upon treatment with an appropriate amine derivative or halogenation of maleimide followed by alkylation. The starting indole derivatives which have no substitution at the 2-position may be obtained by following published procedures and 2-aryl indoles may be prepared from the aryl methyl ketones following the well known Fischer Indole synthetic procedures.

The compounds which constitute this invention and their methods of preparation will appear more fully from a consideration of the

following examples which are given for the purpose of illustration only and are not to be construed as limiting the invention in sphere or scope.

Several intermediate compounds as well as other conventional  
5 starting materials, e.g. II, III and IX; used in the preparation of final products I were generally commercially available. Representative syntheses of some of the final compounds of formula I (wherein in R<sub>1</sub> all substituents are hydrogen unless otherwise mentioned) are provided herein below. The syntheses of some of the intermediates are also  
10 provided such as in examples 1-11, 14, 91-96, 98-102, 104 and 105.

All anhydrous reactions were performed under an atmosphere of nitrogen or argon using dry solvents from Aldrich Sure Seal bottles or freshly distilled solvents. Column chromatography was performed with  
15 silica gel 60 (E M Science, 230-400 mesh) using the mentioned solvent system as eluant. Thin-layer chromatography was conducted on Anatech GFLH or Whatman MK6F silica gel plates. Melting points were determined in an open capillary tube with a Thomas-Hoover melting point apparatus unless otherwise stated and are not corrected. Infrared  
20 spectra were recorded on a Perkin-Elmer 1800 Fourier transform spectrophotometer as thin films or KBr pellets. <sup>1</sup>H NMR spectra and <sup>13</sup>C NMR spectra were recorded on either Bruker AM-300 or JEOL 300 or Bruker AC-300 or 500 MHz NMR instruments and are expressed as parts per million (ppm or δ) from the mentioned solvent as the internal  
25 standard. Coupling constants are in hertz and signals are quoted as apparent singlet (s), triplet (t), quartet (q), multiplet (m), and broad (br). Low resolution mass spectra were determined either on a Finnigan Model 4500 Quadrupole mass spectrometer by direct chemical ionization (DCI)

with isobutane as the positive CI gas, a Finnigan Model SSQ-7000 instrument (neg. or pos. ESI) or on a Kratos MS-25 or Finnigan TSQ-70 instrument (FAB). High resolution mass spectra (HRMS) were determined either on a Kratos MS-50 mass spectrometer using fast atom bombardment with CsI in glycerol as the reference agent or on a Finnigan MAT-900 instrument using electrospray ionization with polypropylene glycol as the reference agent.

To a magnetically stirred solution of 3,4-dibromomaleimide (20.0 g, 78.5 mmol) in acetone (1200 mL) was added potassium carbonate (132 g, 0.954 mol). 4-(t-Butyl)benzyl bromide (24.98 g, 20.2 mL, 110 mmol) was slowly added over 15 min and the reaction mixture was then stirred for 6 h in the dark. The reaction mixture was filtered over a bed of Celite and

washed with acetone (250 mL). Evaporation *in vacuo*, followed by flash chromatography on silica gel with 50% hexane in dichloromethane, gave 22.5 g (71.5%) of the title compound as a white solid. 300 MHz  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  7.45-7.25 (m, 4 H), 4.75 (s, 2 H), 1.32 (s, 9 H); DCI mass spectrum, m/e 399 ( $\text{M}^+$ ); Anal. ### Example 3

2-(2-Benzo[b]thienyl)-5-fluoro-1H-indole (III :  $\text{X}_1 = 5\text{F}$ ;  $\text{X}_2 = \text{H}$ ;  $\text{R}'' = 2$ -benzo[b]thienyl,  $\text{R}' = \text{H}$ )

n-Butyllithium in hexanes (1.6M, 255mL, 0.41 mol) was added in 5 mL portions to a cold ( $4^\circ\text{C}$ ) solution of thianaphthene (47.8g, 0.36 mol) in dry tetrahydrofuran/diethyl ether (1:1, 400 mL) under an atmosphere of nitrogen. The alkyllithium was added at a such a rate that the internal reaction temperature never exceeded  $8^\circ\text{C}$ . After the addition was complete, the reaction mixture was allowed to warm up to ambient temperature where it stirred for 1h before it was cooled back to  $4^\circ\text{C}$  and treated cautiously with a solution of acetaldehyde (50 mL) in dry tetrahydrofuran (50 mL). The mixture was allowed to warm up to room temperature for 0.5h before it was quenched with water and diluted with ethyl acetate. The organic phase was separated, washed with brine, dried and concentrated. The aqueous phase was extracted twice more with ethyl acetate and combined with the original organic extract prior to further workup. Purification of the resultant residue by flash chromatography on silica gel (gradient elution with 7% ethyl acetate in hexanes followed by 15% ethyl acetate in hexanes) afforded 29.25g (46%) of the intermediate alcohol as a pale yellow solid which was carried on directly. The alcohol

(29.15g, 0.16 mol) was dissolved in anhydrous dichloromethane (800 mL) and the reaction mixture was treated with Celite (36g) and pyridinium chlorochromate (35g). After one hour at room temperature, additional dichloromethane (400 mL), Celite  
5 (36g) and PCC (35g) were added. The mixture was stirred further for an additional 1h at room temperature before it was diluted with ether (1L), suction-filtered through a bed of silica gel and concentrated. There was isolated the methyl ketone (27.6g, 96%) as a pure, white solid. Anhydrous sodium acetate (16.6g, 0.20 mol) was added in one portion to a stirred  
10 suspension of 4-fluorophenylhydrazine hydrochloride (32.98g, 0.20 mol) and the methyl ketone (27.5g, 0.156 mol) in absolute ethanol (150 mL). The mixture was refluxed for 2h before it was cooled, diluted with dichloromethane, and washed with saturated sodium bicarbonate solution, 1N hydrochloric acid and brine. Following drying and solvent  
15 evaporation, the residue was recrystallized from hot ethanol to furnish the pure hydrazone (40.08g, 90%) as a yellow solid. The hydrazone (18.3g, 64.4 mmol) was placed into a 500 mL single neck round bottom flask (equipped with a reflux condenser) which contained freshly-fused zinc chloride held under a nitrogen atmosphere. The flask was then placed in a  
20 preheated oil bath (180°C) for 1h. After 1h, the oil bath temperature was allowed to cool to 140°C before the flask was charged cautiously with absolute ethanol. The mixture was refluxed for 6h before it was cooled, diluted with ethyl acetate and washed with 1N hydrochloric acid and brine prior to drying and solvent concentration to 1/3 volume. Suction-

To a magnetically stirred solution of 5-fluoroindole (7.0 g, 51.8 mmol) in anhydrous benzene (125 mL) was added under argon with stirring, methyl magnesium iodide (3.0 M in ether; 18.0 mL, 54.0 mmol).

20 To a solution of 6-fluoroindole (50.0g, 0.37 mol) in anhydrous benzene (1L) under nitrogen was added via syringe ethylmagnesium bromide (3M, 130 mL, 0.43 mol) at a rate which kept the internal temperature between 45-50°C. The mixture was then heated to 50-55°C for 0.5h before a suspension of 2,3-dibromomaleimide (24.9g, 0.093 mol) in  
25 anhydrous benzene was poured into the reaction mixture. The mixture was refluxed for 22h, cooled, diluted with ethyl acetate, and acidified to pH=1 with 1N HCl. The organic phase was then separated, washed with brine, dried and concentrated. The aqueous phase was diluted once more

with ethyl acetate and separated. The resulting organic phase was treated in identical fashion as mentioned above and combined with the original.

Another 50g reaction was performed and combined prior to chromatography. Purification of the combined residues by flash

To a magnetically stirred suspension of core from Example 8 (9.50 g, 17.7 mmol) in anhydrous THF (450 mL) was added over 5-10 min under argon with stirring, sodium bis(trimethylsilyl)amide (1.0 M in THF; 50.0  
25 mL, 2.82 equiv). The resulting deep red solution was stirred at room temperature for 45 min, treated neat via syringe with chlorotrimethylsilane (5.06 mL, 40.0 mmol), and stirred at room temperature for a further 1 h. The reaction mixture was then heated to

reflux, and maintained at reflux while a solution of the 1,2-anhydrosugar IX (13.5 g, 31.2 mmol; see J. Org. Chem. 1993, 58, 343-349) in anhydrous THF (200 mL) was added over 3.5 h via a constant addition funnel. After the addition was completed, the reaction was refluxed for 10 h under argon, treated with a solution of additional 1,2-anhydrosugar IX (800 mg) in anhydrous THF (40 mL) and refluxed further for 2.5 h. The mixture was cooled to room temperature over 45 min, treated with HCl (1.0 N, 280 mL), and stirred for 75 min. The mixture was partitioned between ethyl acetate (2000 mL) and 0.5 N HCl (600 mL). The organic layer was washed with saturated aqueous sodium bicarbonate (300 mL), water (350 mL), and brine (400 mL). The original acidic aqueous layer was extracted with fresh ethyl acetate (600 mL) which was then washed with water (100 mL), and brine (150 mL). The combined organic extracts were dried (Na<sub>2</sub>SO<sub>4</sub>) and rotary evaporated to a volume of about 300 mL, whereupon the resulting yellow precipitate was collected by filtration, washed with ethyl acetate (300 mL), and dried *in vacuo* to give 3.00 g (31.6%) of recovered pure starting core. The filtrate was concentrated *in vacuo*, dissolved in methylene chloride/hexane, and purified by flash chromatography on silica gel using 5-10% ethyl acetate in hexanes. The yellow fractions containing the least polar spot were evaporated to a volume of about 300 mL and let stand overnight to yield 625mg (3.8%) of beautiful yellow prisms of N<sub>12</sub>, N<sub>13</sub>-doubly glycosylated product (structure determined by X-RAY crystallography). An additional 380 mg (2.3%) of the same was obtained from the mother liquor. Further elution with 10-15% ethyl acetate in hexanes gave 9.23 g (55.5%, 81% based on recovered starting core) of analytically pure title compound of formula VIII as a yellow solid. 500 MHz <sup>1</sup>H NMR (d<sub>6</sub>-DMSO) δ 10.85 (brs, 1H), 8.84 (dd, 1H, J = 9.6, 2.7 Hz), 8.75 (dd, 1H, J = 9.6, 2.5 Hz), 7.54 (ddd, 1H, J = 9.1, 9.1, 2.7 Hz), 7.42-7.18 (m,

2,10-Difluoro-12,13-dihydro-13-[2-O-(triethylsilyl)-3,4,6-tris-O-(phenylmethyl)- $\beta$ -D-glucopyranosyl]-6-triethylsilyl-5H-indolo[2,3-

- a]pyrrolo[3,4-c]carbazole-5,7-dione (A= VIII:  $X_1 = X_1' = F$ ;  $X_2 = X_2' = H$ ;  $R_6 = R''' = \text{triethylsilyl}$ ;  $Q = NH$ ;  $PG = \text{benzyl}$ ) and 2,10-difluoro-12,13-dihydro-13-[2-O-(triethylsilyl)-3,4,6-tris-O-(phenylmethyl)- $\beta$ -D-glucopyranosyl]-5H-indolo[2,3-a]pyrrolo[3,4-c]carbazole-5,7(6H)-dione (B= VIII:  $X_1 = X_1' = F$ ;  $X_2 = X_2' = R_6 = H$ ;  $R''' = \text{triethylsilyl}$ ;  $Q = NH$ ;  $PG = \text{benzyl}$ ).

Triethylsilyl triflate (9.0 mL, 40.0 mmol, 20 eq.) was added in one portion to a solution of 2,10-difluoro-12,13-dihydro-13-[3,4,6-tris-O-(phenylmethyl)- $\beta$ -D-glucopyranosyl]-5H-indolo[2,3-a]pyrrolo[3,4-c]carbazole-5,7(6H)-dione (1.60g, 2.0 mmol) in dry pyridine (100 mL). The mixture was stirred in a sealed flask at room temperature for 48h before absolute ethanol (5 mL) was added. After 10 min., the solvent was removed *in vacuo* at room temperature. The residue was then diluted with ethyl acetate and tetrahydrofuran and acidified with 0.1N hydrochloric acid until acidic. Following the separation of the organic phase, the organic phase was washed with brine, dried over anhydrous sodium sulfate, and concentrated. Attempted purification of the residue by flash chromatography (2x) on silica gel (elution with 10% tetrahydrofuran in hexanes for the first time and 40% ether in hexanes the second time) yielded title compound A (1.4g) as a slightly impure yellow foam. The impurity proved to be B. Complete conversion of A to B could be accomplished by dissolving A (1.4g, 1.37mmol) in absolute ethanol (20mL) and treating the solution with ammonium acetate (0.11g, 1.40 mmol) at ambient temperature for 2h. The mixture was then diluted with ethyl acetate and washed successively with saturated sodium bicarbonate solution and brine prior to drying and concentration to dryness. There was isolated title compound B (1.19g, 96%) as a yellow foam.

There was indicated mostly starting material with a small amount of the higher R<sub>f</sub> product spot. ### Example 29

3,9-Difluoro-12,13-dihydro-13-[6-(4N-morpholino)- $\beta$ -D-glucopyranosyl]-5H-indolo[2,3-a]pyrrolo [3,4-c] carbazole-5,7(6H)-dione (Ia:  $X_1=X_1'=F$ ;  $X_2=X_2'=R_6=H$ ;  $R_5=4N$ -morpholino;  $Q=NH$ ;  $R_2-R_4=OH$ ).

To a magnetically stirred solution of the pure product from  
10 example 28 (205 mg, 0.240 mmol) in absolute ethanol (160 mL) was added aqueous potassium hydroxide (4.45 M, 42 mL, 187 mmol). The resulting deep red solution was heated in an open flask until all the ethanol was evaporated and a solid gums out (about 1.5 h). The mixture was cooled under a stream of nitrogen and concentrated HCl (12 N; 17 mL,  
15 204 mmol) was added. The mixture was stirred 5 min and absolute ethanol (90 mL) was added, followed by solid ammonium acetate (85 g). The mixture was heated with stirring in an open flask just below boiling for 2.5-3 h, then to 180 °C (internal temperature of the melt) over about 2 h. The mixture was further heated to 200 °C over 10-15 min, rapidly  
20 cooled under a stream of nitrogen to about 50-60 °C, and digested with water (200 mL), saturated aqueous sodium bicarbonate (200 mL), and ethyl acetate (800 mL). The organic layer was washed with brine (200 mL), the combined aqueous layers extracted with fresh ethyl acetate (300 mL), and the latter extract was washed with brine (100 mL). The combined organic  
25 extracts were dried ( $Na_2SO_4$ ) and evaporated in vacuo. The crude material was dissolved in methanol (400 mL) and treated with anhydrous potassium carbonate (2.0 g) and potassium fluoride dihydrate (1.03 g), and stirred at room temperature for 15 h. The solvent was evaporated in

vacuo, the residue redissolved in methanol (250 mL), treated with 1 N HCl (15 mL), and evaporated in vacuo. The residue was dissolved in absolute ethanol (500 mL), evaporated in vacuo, and this process was again repeated. Recrystallization from 95% ethanol gave 79.6 mg (53%, 2  
5 crops) of the pure title compound as its HCl salt: 500 MHz COSY  $^1\text{H}$  NMR (d<sub>6</sub>-DMSO)  $\delta$  12.67 (brs, 1H), 11.19 (s, 1H), 8.92 (dd, 1H,  $J = 9.7, 2.6$  Hz), 8.79 (dd, 1H,  $J = 9.8, 2.3$  Hz), 8.05 (dd, 1H,  $J = 9.0, 4.5$  Hz), 7.94 (dd, 1H,  $J = 8.7, 4.5$  Hz), 7.46 (ddd, 1H,  $J = 2.5, 8.9, 9.0$  Hz), 7.41 (ddd, 1H,  $J = 2.6, 9.0, 9.1$  Hz), 6.61 (d, 1H,  $J = 8.6$  Hz, 1'H), 3.97 (t, 1H,  $J = 8.8$  Hz, 2'H), 3.91-3.16 (m, 13 H).

To a solution of Dess-Martin periodinane (0.470 g, 1.11 mmol) in 30 mL of dichloromethane was added dropwise a solution of 6-(4-*tert*-butylbenzyl)-2,3,9,10-tetrafluoro-12-(2,3,6-tri-O-benzyl-β-D-glucopyranosyl)indolo[2,3-a][pyrrolo [3,4-c]-carbazole-5,7-dione (0.540 g, 0.55 mmol) in 20 mL of dichloromethane and the mixture was stirred at room temperature under Ar for 1 h. Another 0.470g (1.11 mmol) of Dess-Martin reagent was added and stirring was continued for 2 h. The

5(H)indolo[2,3-a] pyrrolo[3,4-c] carbazole-5,7-dione.

Employing the Mitsunobu procedure described earlier in Example  
10 22, 250 mg (0.465 mmol) of the product from example 6 and 210 mg (0.464 mmol) of 2-Fluoro-3,4,6-Tri-O-benzyl-D-glucopyranose (prepared by treating commercially available Tri-O-benzyl-D-glucal (1.5 g, 3.6 mmol) with xenon difluoride (1.0 g, 5.91 mmol) in acetonitrile (50 mL) and water (5 mL) for 3 h at room temperature. Typical workup followed by flash  
15 chromatography on silica gel with 5% ethyl acetate in methylene chloride gave 380 mg (23.4%) of the pure 2-Fluoro-3,4,6-Tri-O-benzyl-D-glucopyranose. This procedure was a modification of a published method: See T. Hayashi, B. W. Murray, R. Wang, and C.-H. Wong Bioorganic and Medicinal Chemistry, 1997, 5, 497-500.). Following purification by flash  
20 chromatography using 20-60 % methylene chloride in hexane, 120 mg (28%) of reasonably pure glucosylated product was obtained: Removal of the benzyl protecting groups by using transfer hydrogenation conditions (95%EtOH/Cyclohexene/20%Pd(OH)<sub>2</sub>/C, reflux for 6-48hrs) followed by removal of the 4-t-butylbenzyl protecting group under base hydrolysis  
25 conditions (4.45M KOH, EtOH/reflux; conc. Hcl; NH<sub>4</sub>OAc/EtOH/heat for 8-48hrs) provided after purification by flash chromatography on silica gel with acetone : methylene chloride : ethyl acetate, followed by further purification on Sephadex LH-20 in methanol gave 15 mg (39% for the 2 deblocking steps) of the pure title compound as a yellow-orange solid: 300

5 Example 10 (3.35 g, 3.25 mmol) in absolute ethanol (600 mL) was added aqueous potassium hydroxide (4.45 M, 60.0 mL, 267 mmol). The resulting deep red solution was heated in an open flask until about one-half of the ethanol was evaporated (about 3 h). The mixture was cooled under a stream of nitrogen and concentrated HCl (12 N; 175 mL) was added. The  
10 mixture was stirred 15 min and then partitioned with water (300 mL) and ethyl acetate (800 mL). The organic layer was washed with water (300 mL), saturated aqueous sodium bicarbonate (300 mL), and brine (300 mL), dried ( $\text{Na}_2\text{SO}_4$ ), and evaporated in vacuo. The resulting solid anhydride was treated with ethylene diamine (50 mL) and heated to boiling for about 4-5
